

My Report

Me

Tuesday 18th March, 2025

Abstract

We give a toy example of a report in *literate programming* style. The main advantage of this is that source code and documentation can be written and presented next to each other. We use the listings package to typeset Haskell source code nicely.

1 How to use this?

To generate the PDF, open `report.tex` in your favorite \LaTeX editor and compile. Alternatively, you can manually do `pdflatex report; bibtex report; pdflatex report; pdflatex report` in a terminal.

You should have stack installed (see <https://haskellstack.org/>) and open a terminal in the same folder.

- To compile everything: `stack build`.
- To open ghci and play with your code: `stack ghci`
- To run the executable from Section 5: `stack build && stack exec myprogram`
- To run the tests from Section ??: `stack clean && stack test --coverage`

2 The library files

3 The AC3Solver library

This section describes a module which we will import later on.

```
module AC3Solver where

import Control.Monad.Writer
  ( runWriter, MonadWriter(tell), Writer )
```

To start of, we define the AC3 instance. For each agent, we have a set of agents of type `a`. An AC3 instance then contains a list of constraints `constraintAA`, and a list of domains. Each `constraintAA` contains a pair of agents (X,Y), and then a function, such as `(==)`, which is the constraint on the arc from X to Y. Each `Domain` item contains an agent, and then a list of values of type `b`.

We may have multiple constraints for a pair of agents (X,Y), such as both `(>)` and `(>=)`. The programme however expects that each agent has exactly 1 domain specified for it, and each constraint (X,Y) should have some (possibly empty) domain assigned to it.

```
data AC3 a b = AC3 {
  -- Constraint should take values from the first & second agents as params x & y resp.
  -- in \x,y-> x ==? y.
  -- We should allow for multiple constraints for (X,Y), eg. both (x > y) AND (x < y) in
  -- the set.
  cons :: [ConstraintAA a b],
  -- Assume we have 1 domain list for each variable. (TODO: Check for this? )
  domains :: [Domain a b] }

type Domain a b = (Agent a, [b])
type ConstraintAA a b = (Agent a, Agent a, Constraint b)
type Constraint a = a -> a -> Bool

type Agent a = a
```

For each constraint (X,Y,f), we want to check for each value in the domain of X whether there is a value in Y's domain such that `f x y` is satisfied. Values of X for which there is no such

value in Y are removed from X's domain. We make use of the Writer monad to do an $O(1)$ lookup to see if we removed items from X's domain.

```
-- Return the elements of xs for which there exist a y \in ys, such that c x y holds.
-- Using the writer monad, we also give a O(1) method to check whether we altered x's
  domain after termination.
checkDomain :: [a] -> [a] -> Constraint a -> Writer String [a]
checkDomain [] _ _ = return []
checkDomain (x:xs) ys c = do
  rest <- checkDomain xs ys c
  if not $ null [ y' | y'<-ys, c x y'] then return $ x:rest
  else tell "Altered domain" >> return rest -- This is nicely formatted for readability,
    it could just be "." or whatever.
```

Each time we call `iterate`, we start off by looking for the domains of agents X & Y for our constraint (X,Y). Once we find these, we are likely to replace the original domain for X with a reduced one. We use `popXy` and `popX` to find the domains for X & Y, and at the same time we also remove the *old* domain for X. Using this is 1 walk through the list, and saves us 2 walks. (Separate lookup for y, and a walk to delete the old x.) Once we have checked the current constraint, we then add back the *new* domain for X.

```
-- PRE: x is an element of (a:as)
popX :: Eq a => Agent a -> [Domain a b] -> ([b], [Domain a b] )
popX _ [] = undefined -- should not occur.
popX x (a@(aA, aD):as) = if x == aA then (aD,as) else let (x', as') = popX x as in (x', a:
  as')

-- PRE: x != y; x,y are elements of (a:as).
-- (else, this is not a binary constraint but a unary one.)
popXy :: Eq a => Agent a -> Agent a -> [Domain a b] -> ([b], [b], [Domain a b] )
popXy _ _ [] = undefined -- should not occur.
popXy x y (a@(aA, aD):as)
  | x == aA = let -- we want to REMOVE a from the list.
    -- search through the rest of the list and return y's domain.
    yDomain = head [b' | (a',b')<-as, y==a' ]
    in (aD, yDomain, as)
  | y == aA = let (retX, retAs) = popX x as in (retX, aD, a:retAs)
  | otherwise = let (retX, retY, retAs) = popXy x y as in (retX, retY, a:retAs)
```

We now come to the main part of the algorithm. The `iterateAC3` function runs as long as the queue of constraints is not empty, starting with the original set of constraints. We get the domains of X & Y, and remove the *old* domains of X. We then run `checkDomain`, and add the new domain of X back to the list of domains. If X's domain was altered, then we add all constraints of the form (Y,X) to the back of the queue.

```
ac3 :: (Ord a, Ord b) => AC3 a b -> [Domain a b] -- return a list of domains.
ac3 m@(AC3 c d) = let
  queue = c -- put each constraint into the queue. -- TODO: implement this better, eg a
    priority queue?
  in iterateAC3 m queue d

iterateAC3 :: (Ord a, Ord b) => AC3 a b -> [ConstraintAA a b] -> [Domain a b] -> [Domain a
  b]
iterateAC3 _ [] d = d
iterateAC3 m@(AC3 fullCS _) ((x,y,c):cs) d = let
  (xDomain, yDomain, alteredD) = popXy x y d
  (newX, str) = runWriter $ checkDomain xDomain yDomain c
  -- In a lens, we could do this with "modify (\ (a,_) -> (a, newX))"
  newDomains = (x, newX) : alteredD
  z = if null str then cs else cs ++ [c' | c'@(y1,x1,_)<-fullCS, y1==y, x1==x ] -- take
    all constraints of the form (y,x, c)
  in iterateAC3 m z newDomains
```

```
module NQueens where
```

```

3.1 The Graph Colouring library

```

--{-# LANGUAGE LambdaCase #-} -- todo remove? if not using data.graph.read...
module GraphCol where

import Control.Monad (when)
import Data.Char (toUpper)
import Data.Graph
--import Data.Graph.Read
import Data.List
import Text.Read (readMaybe)
import Test.QuickCheck

import AC3Solver

```

```

import Backtracking
import Scheduling (parseInput)

-- We define a newtype, so that we can generate arbitrary instances.
newtype GraphCol = GC (AC3 Vertex Int)

seqPair :: (Gen a, Gen a) -> Gen (a,a)
seqPair (ma, mb) = ma >>= \a -> mb >>= \b -> return (a,b)

-- (Seems graphs don't already have an arbitrary instance...)
instance Arbitrary GraphCol where
  arbitrary = sized arbitGraphColN where
    arbitGraphColN n = do
      nColours <- choose (1, max (n `div` 2) 1) -- we require n to be > 0
      sizeV <- choose (0, n) -- we make vertices 0..sizeV INCLUDING SIZEV!!
      sizeE <- choose (0,n)
      e <- sequence [seqPair (choose (0, sizeV), choose (0, sizeV)) | _<- [0..sizeE]]
      -- we do not want edges (x,x)
      let nonRefle = filter (uncurry (/=)) e
      let g = buildG (0, sizeV) nonRefle
      return $ convertGraphToAC3 g nColours --return $ convertGraphToAC3 g n

instance Show GraphCol where
  --show :: GraphCol -> String
  show (GC (AC3 c d)) = let
    strCon = "[" ++ makeShow c ++ "]" where
      makeShow [] = ""
      makeShow ((x,y,_) : cs) =
        "(" ++ show x ++ ", " ++ show y ++ ", (/=))"
        ++ if not $ null cs then ", " ++ makeShow cs else ""
    strD = show d
  in "GC (AC3 " ++ strCon ++ " " ++ strD ++ " )"

```

We define a method to convert a graph into an instance of `GraphCol`, and vice versa. Note that graph colouring concerns *undirected* graphs while the `Graph` library concerns *directed* graphs. As a result, `g == ac3ToGraph $ convertGraphToAC3 g n` (for any $n > 0$) is NOT guaranteed to hold.

```

-- NOTE: The Graph library uses *directed* graphs.
--       We add both (x,y,/=) and (y,x,/=), as graph colouring concerns Undirected graphs.
-- Create an instance with colours [0..(n-1)]
-- PRE: n >= 1
convertGraphToAC3 :: Graph -> Int -> GraphCol
convertGraphToAC3 g n = let
  agents = vertices g
  constr = [(x,y, (/=)) | (x,y)<-edges g]
  in GC $ AC3
    (constr ++ reverseCons constr)
  -- In graph colouring, we want to check both X's domain to Y, and Y's to X.
  ((head agents, [0]) : [(a, [0..(n-1)]) | a<-tail agents])

-- Help function: If we have an edge (x,y), we need both (x,y, /=) and (y,x,/=) as
-- constraints.
reverseCons :: [(a,b,c)] -> [(b,a,c)]
reverseCons = map \(a,b,c) -> (b,a,c))

ac3ToGraph :: GraphCol -> Graph
ac3ToGraph (GC (AC3 c d)) = let
  v = [a | (a,_)<-d]
  e = nub [ (a,b) | (a,b,_)<-c ] -- If we originally had (x,y) AND (y,x) in our graph,
  -- then c contains each twice.
  in buildG (foldr min 0 v, foldr max minBound v) e

module Sudoku where

import Data.List (intercalate)
import AC3Solver ( AC3 (..), ac3, ConstraintAA, Domain )

```

This file contains the implementation of Sudoku puzzles, printing Sudoku boards, and calling the AC3 solver on puzzles.

The constraints on any given cell are: 1. it must contain a distinct number from other cells in the same row, 2. it must contain a distinct number from other cells in the same column, 3. it

must contain a distinct number from other cells in the same 3x3 box.

An *Agent* is represented by a cell, which in-turn is represented as a tuple (i, j) where i is the row number and j is the column number.

```
-- Encode all possible cells in a 9x9 grid
allCells :: [(Int, Int)]
allCells = [(i,j) | i <- [1..9], j <- [1..9]]

sameRow :: (Int, Int) -> (Int, Int) -> Bool
sameRow (x1,_) (y1,_) = x1 == y1

sameCol :: (Int, Int) -> (Int, Int) -> Bool
sameCol (_,x2) (_,y2) = x2 == y2

sameBox :: (Int, Int) -> (Int, Int) -> Bool
sameBox (x1,y1) (x2,y2) = (x1 - 1) 'div' 3 == (x2 - 1) 'div' 3 && (y1 - 1) 'div' 3 == (y2 - 1) 'div' 3
-- for all x: (fst x - 1) in {0,1,2} (box row)
-- for all y: (snd y - 1) in {0,1,2} (box column)
-- when both the box row and box column are the same for x and y, they are in the same box.

-- All cells must obey the three constraints.
sudokuConstraints :: [ConstraintAA (Int, Int) Int]
sudokuConstraints =
    [(i, j, (/=)) | i <- allCells, j <- allCells, i /= j, i 'sameRow' j]
  ++ [(i, j, (/=)) | i <- allCells, j <- allCells, i /= j, i 'sameCol' j]
  ++ [(i, j, (/=)) | i <- allCells, j <- allCells, i /= j, i 'sameBox' j]

-- The domain will change depending on the puzzle being solved. Some cells should have
  fixed values.
-- Each cell can take on a value from 1 to 9.
sudokuDomains :: [Domain (Int, Int) Int]
sudokuDomains = [(i, [1..9]) | i <- allCells]

-- An empty Sudoku puzzle (no cells filled in)

sudokuMain = undefined--AC3 sudokuConstraints sudokuDomains
```

Using the ‘sudokuConstraints’ as a backbone we can define our own sudoku puzzle. It’s quite tedious because it requires us to specify the initial grid. The particular example below is a Sudoku puzzle with a unique solution.

```
-- Define the initial grid
startingCellsUnique :: [Domain (Int, Int) Int]
startingCellsUnique = [
    ((1,3), [1]),
    ((1,5), [6]),
    ((1,9), [4]),
    ((2,1), [8]),
    ((2,4), [1]),
    ((2,6), [4]),
    ((2,8), [6]),
    ((3,2), [3]),
    ((3,7), [8]),
    ((3,9), [5]),
    ((4,1), [7]),
    ((4,3), [8]),
    ((4,5), [2]),
    ((4,9), [3]),
    ((5,2), [6]),
    ((5,3), [3]),
    ((5,7), [1]),
    ((5,8), [2]),
    ((5,9), [9]),
    ((6,5), [1]),
    ((7,1), [3]),
    ((7,7), [2]),
    ((7,9), [8]),
    ((8,1), [1]),
    ((8,3), [4]),
```

```

    ((8,5), [5]),
    ((8,6), [9]),
    ((8,7), [3]),
    ((9,2), [7]),
    ((9,4), [8]),
    ((9,6), [3]),
    ((9,7), [5]),
    ((9,8), [9]),
    ((9,9), [1])
]

-- Combine the starting values with the rest of the (empty) cells
sudokuExampleDomainUnique :: [Domain (Int, Int) Int]
sudokuExampleDomainUnique = startingCellsUnique ++ [(i, [1..9]) | i <- allCells, i `notElem`
    ' map fst startingCellsUnique]

sudokuExampleUnique :: AC3 (Int, Int) Int
sudokuExampleUnique = AC3 sudokuConstraints sudokuExampleDomainUnique

```

Instead of specifying our own sudoku puzzles we can leverage a repository of sudoku puzzles. Below is the code needed to load sudoku puzzles.

```

-- Read a Sudoku puzzle from a file
readSudokuFromFile :: FilePath -> IO [Domain (Int, Int) Int]
readSudokuFromFile filepath = do
    contents <- readFile filepath
    let rows = lines contents
    return (parseSudokuDomains rows)

-- Parse the file contents into domain representation
parseSudokuDomains :: [String] -> [Domain (Int, Int) Int]
parseSudokuDomains rows = cellDomains where
    -- Convert characters to domain values
    charToDomain :: Char -> [Int]
    -- Dots represent empty cells, their domain contains all possible values
    charToDomain '.' = [1..9]
    -- Digits represent fixed cells, their domain contains only that value
    charToDomain c = if c >= '1' && c <= '9' then [read [c]] else [1..9]

    -- Return a list of domains for each cell
    cellDomains = [((i, j), charToDomain c) |
        (i, row) <- zip [1..9] (take 9 rows), -- rows :: [String] where each
        string is a row
        (j, c) <- zip [1..9] (take 9 row)]

-- Create a AC3 formatted Sudoku puzzle from a file
loadSudokuPuzzle :: String -> IO (AC3 (Int, Int) Int)
loadSudokuPuzzle fileName = do
    let filepath = "sudokuPuzzles/" ++ fileName ++ ".sud"
    cellDomains <- readSudokuFromFile filepath
    return (AC3 sudokuConstraints cellDomains)

```

Below are two functions that take a file (name) as input and does: - 'solveSudokuFromFile': loads a sudoku puzzle from a file, runs AC3, and prints the initial and final state of the puzzle. - 'computeReductionFromFile': loads a sudoku puzzle from a file, runs AC3, and computes the average domain size before and after running AC3.

Note the input to both of the above should be a **file name**, which means one of the following: - "easy1", "easy2", ..., "easy50", - "hard1", "hard2", ..., "hard95", - "impossible", "Mirror", "Times1".

```

-- Load, run AC3, and print a Sudoku puzzle
solveSudokuFromFile :: String -> IO ()
solveSudokuFromFile fileName = do
    puzzle <- loadSudokuPuzzle fileName
    putStrLn "Initial puzzle:"

```

```

    printSudokuPuzzle puzzle
    putStrLn "\nAfter applying AC3:"
    printSudokuSolution puzzle

-- Compute the average domain size before and after running AC3
computeReductionFromFile :: String -> IO (Float, Float)
computeReductionFromFile fileName = do
    puzzle <- loadSudokuPuzzle fileName
    return (computeReduction puzzle)

```

The code above relied on some pretty-printing and reduction computation, which are defined below.

```

-- Visualize a Sudoku board based on current domains
visualizeSudoku :: [Domain (Int, Int) Int] -> String
visualizeSudoku domains' = unlines (
    horizontalline : concatMap formatRow [1 .. 9]
)
where
    -- Get the domain for a specific cell
    getDomain i j =
        case [d | ((i', j'), d) <- domains', i' == i, j' == j] of
            (d:_) -> d
            [] -> [1..9] -- Default domain if not specified

    -- Display a cell: single digit if domain has 1 element, empty otherwise
    cellValue i j =
        let domain' = getDomain i j
        in if length domain' == 1
            then show (head domain')
            else " "

    -- Horizontal line patterns
    horizontalline = "+---+---+---+---+---+---+---+---+"
    thickLine = "+++++ +++++ +++++ +++++ +++++ +++++ +++++ +++++"

    -- Format a row with appropriate separators
    formatRow i =
        let rowStr = "|" ++ intercalate " | " [cellValue i j | j <- [1..9]] ++ " |"
        separator = if i `mod` 3 == 0 && i /= 9 then thickLine else horizontalline
        in [rowStr, separator]

-- Function to print the initial state of a Sudoku puzzle
printSudokuPuzzle :: AC3 (Int, Int) Int -> IO ()
printSudokuPuzzle (AC3 _ domains') = do
    putStrLn (visualizeSudoku domains')

-- Function to run and print a Sudoku solution
printSudokuSolution :: AC3 (Int, Int) Int -> IO ()
printSudokuSolution puzzle = do
    let solution = ac3 puzzle
    putStrLn (visualizeSudoku solution)

```

```

-- Compute the amount of reduction in domain size before and after applying AC-3
computeReduction :: AC3 (Int, Int) Int -> (Float, Float)
computeReduction puzzle = (fromIntegral originalSize/81, fromIntegral reducedSize/81)
    where
        originalSize = sum (map length (getDomains puzzle))
        reducedSize = sum (map (length . snd) (ac3 puzzle)) -- Using AC-3 algorithm to reduce
            the domains

-- Extract the domains of each cell from a sudoku puzzle
getDomains :: AC3 (Int, Int) Int -> [[Int]]
getDomains (AC3 _ domains') = map snd domains'

```

4 The Main file

5 Wrapping it up in an executable

We will now use the library from Section ?? in a program.

```
module Main where

import Text.Read (readMaybe)

import Basics
import GraphCol
import Knapsack
import Scheduling
import Sudoku
import NQueens
import ZebraPuzzle

getChoice :: IO Int
getChoice = do
  putStr "Choose one of the following options: \n\
    \1: Graph Colouring \n\
    \2: N-Queens \n\
    \3: Scheduling \n\
    \4: Sudoku \n\
    \5: Zebra Puzzle \n"
  choice <- getLine
  case readMaybe choice of
    Nothing -> do
      putStrLn "Invalid choice, please try again."
      getChoice
    Just n ->
      if n > 0 && n < 6 then return n else do
        putStrLn "Invalid choice, please try again."
        getChoice

main :: IO ()
main = do
  putStrLn "Hello!"
  --print somenumbers
  --print (map funnyfunction somenumbers)
  --myrandomnumbers <- randomnumbers
  --print myrandomnumbers
  --print (map funnyfunction myrandomnumbers)
  --putStrLn "GoodBye"

  -- Get choice
  choice <- getChoice
  case choice of
    1 -> graphColMain
    2 -> nQueensMain
    3 -> schedulingMain
    4 -> sudokuMain
    5 -> zebraPuzzleMain
    _ -> undefined
```

We can run this program with the commands:

```
stack build
stack exec myprogram
```

The output of the program is something like this:

Hello!

```

[1,2,3,4,5,6,7,8,9,10]
[100,100,300,300,500,500,700,700,900,900]
[1,3,0,1,1,2,8,0,6,4]
[100,300,42,100,100,100,700,42,500,300]
GoodBye

```

6 The test file(s)

7 AC3 tests

```

module Main where

```

8 Conclusion

Finally, we can see that [LW13] is a nice paper.
